**Even Semester (Jan-June 2022)**

**Submitted To:**  
**Mrs. Shivani Rohilla**  
**Assistant Professor**  
**Department of CSE**  
**SRM-IST**

**Submitted By:**  
**Mitali Mathur**  
**(RA1911003030169)**  
**CSE – III yr - G**

## **BONAFIDE CERTIFICATE**

*Certified to be the bonafide record of work done by Mitali Mathur  
Of 6<sup>th</sup> semester 3<sup>rd</sup> year B.TECH degree course in SRM INSTITUTE OF SCIENCE &  
TECHNOLOGY, DELHI-NCR Campus for the Department of **Computer Science &  
Engineering**, in Artificial Intelligence Laboratory during the academic year 2021-22.*

**Lab In charge**

**Head of the department**

*Submitted for end semester examination held on \_\_/\_\_\_\_/\_\_\_\_ at SRM INSTITUTE OF  
SCIENCE & TECHNOLOGY, DELHI-NCR Campus.*

Exp. No.	Title of Experiment	Page No.	Date of Experiment	Date of Completion of Experiment	Teacher's Signature
1	Implementation of Toy problem .Example- Implement water jug problem	5-13			
2	Developing Agent Program for Real World Problem.	14-17			
3	Implementation of Constrain satisfaction problem, Example: Implement N- queen Problem	18-19			
4	To Implementation and Analysis of BFS and DFS for Application.	20-21			
5	To implement Best first search and A* algorithm.	22-29			
6	To implement Minimax Algorithm.	30-31			
7	Implementation of unification and resolution for real world problems.	32-33			
8	Implementation of knowledge representation schemes – use cases.	34-36			
9	Implementation of uncertain methods for an application.	37			
10	Implementation of block world problem.	38-39			
11	Implementation Of learning algorithm	40-43			
12	Development of ensemble model	44-45			
13	Implementation of NLP Program	46			

14	Deep learning Project in Python	47-48			
----	---------------------------------	-------	--	--	--

## Experiment 1

- **Aim** – Implementation of Toy problem  
Example-Implement water jug problem.

- **Algorithm** –

Rule	State	Process
1	$(X, Y \mid X < 4)$	$(4, Y)$ {Fill 4-gallon jug }
2	$(X, Y \mid Y < 3)$	$(X, 3)$ {Fill 3-gallon jug }
3	$(X, Y \mid X > 0)$	$(0, Y)$ {Empty 4-gallon jug }
4	$(X, Y \mid Y > 0)$	$(X, 0)$ {Empty 3-gallon jug }
5	$(X, Y \mid X + Y \geq 4 \wedge Y > 0)$	$(4, Y - (4 - X))$ {Pour water from 3-gallon jug into 4-gallon jug until 4-gallon jug is full }
6	$(X, Y \mid X + Y \geq 3 \wedge X > 0)$	$(X - (3 - Y), 3)$ {Pour water from 4-gallon jug into 3-gallon jug until 3-gallon jug is full }
7	$(X, Y \mid X + Y \leq 4 \wedge Y > 0)$	$(X + Y, 0)$ {Pour all water from 3-gallon jug into 4-gallon jug }
8	$(X, Y \mid X + Y \leq 3 \wedge X > 0)$	$(0, X + Y)$ {Pour all water from 4-gallon jug into 3-gallon jug }
9	$(0, 2)$	$(2, 0)$ {Pour 2 gallon water from 3 gallon jug into 4 gallon jug }

- **Code** –  

```

print("Water jug problem")
x=int(input("Enter X : "))
y=int(input("Enter Y : "))
while True:
    rn=int(input("Enter the rule no. : "))
    if rn==2:
        if y<3:
            x=0

```

```

        y=3
    if rn==3:
        if x>0:
            x=0
            y=3
    if rn==5:
        if x+y>4:
            x=4
            y=y-(4-x)
    if rn==7:
        if x+y<4:
            x=x+y
            y=0
    if rn==9:
        x=2
        y=0
    print("X=",x)
    print("Y=",y)
    if x==2:
        print("The result is a goal state")
        break

```

## • Result –

The screenshot shows a web browser with the URL `programiz.com/python-programming/online-compiler/`. The page features the Programiz logo and an Adobe banner. The main area contains a code editor with a Python script for a water jug problem. The script initializes `x=0` and `y=3`, then enters a loop where it checks for goal states based on rule numbers 3, 5, 7, and 9. Rule 3 checks if `x > 0` and sets `x=0`. Rule 5 checks if `x+y > 4` and sets `x=4` and `y=y-(4-x)`. Rule 7 checks if `x+y < 4` and sets `x=x+y` and `y=0`. Rule 9 checks if `x==2` and `y==0`, and if true, prints "The result is a goal state" and breaks the loop. The shell on the right shows the program's execution, prompting for rule numbers and displaying the final goal state.

## TIC TAC TOE

import random

class TicTacToe:

```

def __init__(self):
    self.board = []

def create_board(self):
    for i in range(3):
        row = []
        for j in range(3):
            row.append('-')
        self.board.append(row)

def get_random_first_player(self):
    return random.randint(0, 1)

            win = False
            break
    if win:
        return win
    return False
    for row in self.board:
        for item in row:
            if item == '-':
                return False
    return True

```

```

def is_board_filled(self):

    for row in self.board:

        for item in row:

            if item == '-':

                return False

    return True

def swap_player_turn(self, player):

    return 'X' if player == 'O' else 'O'

def show_board(self):

    for row in self.board:

        for item in row:

            print(item, end=" ")

        print()

def start(self):

    self.create_board()

    player = 'X' if self.get_random_first_player() == 1 else 'O'

    while True:

        print(f"Player {player} turn")

        self.show_board()

        # taking user input

        row, col = list(

            map(int, input("Enter row and column numbers to fix spot: ").split()))

        print()

        # fixing the spot

        self.fix_spot(row - 1, col - 1, player)

        # checking whether current player is won or not

```

```

        if self.is_player_win(player):

            print(f"Player {player} wins the game!")

            break

        # checking whether the game is draw or not

        if self.is_board_filled():

            print("Match Draw!")

            break

        # swapping the turn

        player = self.swap_player_turn(player)

        # showing the final view of board

        print()

        self.show_board()

# starting the game

tic_tac_toe = TicTacToe()

tic_tac_toe.start()

```

## RESULT:

The screenshot shows a web browser with the Programiz Python Online Compiler. The code editor contains the following Python code:

```

106         print(f"Player {player} wins the game!")
107         break
108
109         # checking whether the game is draw or not
110         if self.is_board_filled():
111             print("Match Draw!")
112             break
113
114         # swapping the turn
115         player = self.swap_player_turn(player)
116
117         # showing the final view of board
118         print()
119         self.show_board()
120
121
122 # starting the game
123 tic_tac_toe = TicTacToe()
124 tic_tac_toe.start()

```

The Shell output shows the game execution:

```

0 - -
- - -
Enter row and column numbers to fix spot: 1 3
Player X turn
X X 0
0 - -
- - -
Enter row and column numbers to fix spot: 2 2
Player O turn
X X 0
0 X -
- - -
Enter row and column numbers to fix spot: 3 3
Player X turn
X X 0
0 X -
- - 0
Enter row and column numbers to fix spot: 3 2
Player X wins the game!

```

## Experiment 3

- **Aim** – Implementation of Constraint satisfaction problem  
Example: Implement N- queen Problem

- **Algorithm** –  
while there are untried configurations  
{  
    generate the next configuration  
    if queens don't attack in this configuration then  
    {  
        print this configuration;  
    }  
}

- **Code** –  
global N  
N=int(input("enter no of queens : "))  
def printSolution(board):  
    for i in range(N):  
        for j in range(N):  
            print(board[i][j],end=" ")  
        print(" ")  
def isSafe(board,row,col):  
    for i in range(col):  
        if board[row][i]=='Q':  
            return False  
    for i,j in zip(range(row,-1,-1), range(col,-1,-1)):  
        if board[i][j]=='Q':  
            return False  
    for i,j in zip(range(row,N,1), range(col,-1,-1)):  
        if board[i][j]=='Q':  
            return False  
  
    return True  
def solveNQUtil(board,col):  
    if col>=N:  
        return True  
    for i in range(N):  
        if isSafe(board,i,col):  
            board[i][col]='Q'  
            if solveNQUtil(board,col+1) == True:  
                return True  
            board[i][col]=0  
    return False  
def solveNQ():  
    board = [[0 for i in range(N)] for j in range(N)]  
    if solveNQUtil(board,0)==False:

```

        print("Solution does not exist")
        return False
    printSolution(board)
    return True
solveNQ()

```

- **RESULT:**

The screenshot shows an online Python IDE with the following code in `main.py`:

```

35     return False
36
37 def solveNQ():
38     board = [[0 for i in range(N)] for j in range(N)]
39
40     if solveNQUtil(board,0)==False:
41         print("Solution does not exist")

```

The output of the program is as follows:

```

enter no of queens :
8
Q 0 0 0 0 0 0 0 0
0 0 0 0 0 0 Q 0
0 0 0 0 Q 0 0 0
0 0 0 0 0 0 0 Q
0 Q 0 0 0 0 0 0
0 0 0 Q 0 0 0 0
0 0 0 0 0 Q 0 0
0 0 Q 0 0 0 0 0

```

## Experiment 4

- Aim – To Implementation and Analysis of BFS and DFS for Application.

- Algorithm –

1. Create a node list (Queue) that initially contains the first node N and mark it as visited.
2. Visit the adjacent unvisited vertex of N and insert it in a queue.
3. If there are no remaining adjacent vertices left, remove the first vertex from the queue mark it as visited, display it.
4. Repeat step 1 and step 2 until the queue is empty or the desired node is found.

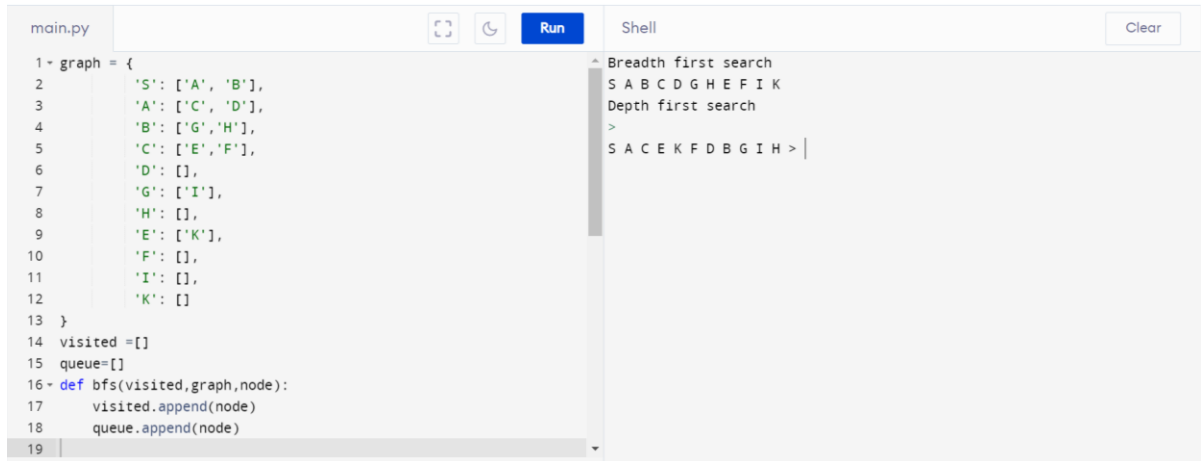

- Code –

```
graph = {
    'S': ['A', 'B'],
    'A': ['C', 'D'],
    'B': ['G', 'H'],
    'C': ['E', 'F'],
    'D': [],
    'G': ['T'],
    'H': [],
    'E': ['K'],
    'F': [],
    'T': [],
    'K': []
}
visited=[]
queue=[]
def bfs(visited,graph,node):
    visited.append(node)
    queue.append(node)

    while queue:
        P=queue.pop(0)
        print(P,end=" ")
        for neighbour in graph[P]:
            if neighbour not in visited:
                visited.append(neighbour)
                queue.append(neighbour)
avisit=set()
def dfs(avisit,graph,node):
    if node not in avisit:
        print(node,end=" ")
        avisit.add(node)
        for neighbour in graph[node]:
```

```
        dfs(avisit,graph,neighbour)
print("Breadth first search")
bfs(visited,graph,'S')
print("\nDepth first search")
dfs(avisit,graph,'S')
```

- **RESULT:**

The screenshot displays a code editor with a file named 'main.py'. The code defines a graph with 11 nodes (A-K) and their neighbors, then performs a Breadth First Search (BFS) starting from node 'S' and a Depth First Search (DFS) starting from node 'S'. The BFS output shows the sequence of nodes visited: S A B C D G H E F I K. The DFS output shows the sequence of nodes visited: S A C E K F D B G I H. The code is as follows:

```
1 = graph = {
2     'S': ['A', 'B'],
3     'A': ['C', 'D'],
4     'B': ['G', 'H'],
5     'C': ['E', 'F'],
6     'D': [],
7     'G': ['I'],
8     'H': [],
9     'E': ['K'],
10    'F': [],
11    'I': [],
12    'K': []
13 }
14 visited =[]
15 queue=[]
16 def bfs(visited,graph,node):
17     visited.append(node)
18     queue.append(node)
```

The shell window output is as follows:

```
^ Breadth first search
S A B C D G H E F I K
Depth first search
>
S A C E K F D B G I H > |
```

## **Experiment 5**

- **Aim-**To implement Best First Search and A\* algorithm.

- **Algorithm-**

1. **Best First Search-**

Step 1: Place the starting node into the OPEN list.

Step 2: If the OPEN list is empty, Stop and return failure.

Step 3: Remove the node  $n$ , from the OPEN list which has the lowest value of  $h(n)$ , and places it in the CLOSED list.

If node  $n$  is goal then return

else

Step 4: Expand the node  $n$ , and generate and check the successors of node  $n$ . and find whether any node is a goal node or not. If any successor node is goal node, then return success and terminate the search, else proceed to Step 5.

Step 5: For each successor node, algorithm checks for evaluation function  $f(n)$ , and then check if the node has been in either OPEN or CLOSED list. If the node has not been in both list, then add it to the OPEN list.

Step 6: Return to Step 2.

2. **A\*-**

Step1: Place the starting node in the OPEN list.

Step 2: Check if the OPEN list is empty or not, if the list is empty then return failure and stops.

Step 3: Select the node from the OPEN list which has the smallest value of evaluation function ( $g+h$ ), if node  $n$  is goal node then return success and stop, otherwise

Step 4:Expand node  $n$  and generate all of its successors, and put  $n$  into the closed list. For each successor  $n'$ , check whether  $n'$  is already in the OPEN or CLOSED list, if not then compute evaluation function for  $n'$  and place into Open list.

Step 5: Else if node  $n'$  is already in OPEN and CLOSED, then it should be attached to the back pointer which reflects the lowest  $g(n')$  value.

Step 6: Return to Step 2.

- **Code-**

2.If Player ='Max'                                     // for Maximizer Player
    set  $\alpha = -\infty$                                 // worst case value for MAX
    for each child of node do
    value= minimax(child, depth-1, 'MIN')
     $\alpha = \max(\alpha, \text{Value})$                         //gives Maximum of the values
return ( $\alpha$ )
    else                                                // for Minimizer player
    set  $\alpha = +\infty$                                     // worst case value for MIN
    for each child of node do
    value= minimax(child, depth-1, 'MAX')
     $\alpha = \min(\alpha, \text{Value})$                         //gives minimum of the values
return ( $\alpha$ )
```

- Code –

```
import math
def minimax (curDepth, nodeIndex, maxTurn, scores,targetDepth) :
    if(curDepth==targetDepth):
        return scores[nodeIndex]
    if(maxTurn):
        return max(minimax(curDepth+1,
nodeIndex*2,False,scores,targetDepth),minimax(curDepth+1,
nodeIndex*2+1,False,scores,targetDepth))
    else:
        return min(minimax(curDepth+1,
nodeIndex*2,True,scores,targetDepth),minimax(curDepth+1,
nodeIndex*2+1,True,scores,targetDepth))
scores=[-1,4,2,6,-3,-5,0,7]
treeDepth=math.log(len(scores),2)
print("Optimal value is : ",end=" ")
print(minimax(0,0,True,scores,treeDepth))
```

## • RESULT:

Screenshot of a Python online compiler showing the implementation of a minimax algorithm. The code defines a `minimax` function that recursively evaluates the optimal value from a list of scores. The terminal output shows the optimal value is 4.

```

1 import math
2 def minimax (curDepth, nodeIndex, maxTurn, scores,targetDepth) :
3     if (curDepth==targetDepth):
4         return scores[nodeIndex]
5     if (maxTurn):
6         return max(minimax(curDepth+1, nodeIndex*2,False,scores
7             ,targetDepth),minimax(curDepth+1, nodeIndex*2+1,False
8             ,scores,targetDepth))
9     else:
10        return min(minimax(curDepth+1, nodeIndex*2,True,scores
11            ,targetDepth),minimax(curDepth+1, nodeIndex*2+1,True
12            ,scores,targetDepth))
13
14 scores=[-1,4,2,6,-3,-5,0,7]
15 treeDepth=math.log(len(scores),2)
16 print("Optimal value is : ",end=" ")
17 print(minimax(0,0,True,scores,treeDepth))

```

Optimal value is : 4

## Experiment 7

- Aim – Implementation of unification and resolution for real world problems.
- Algorithm–

### Prolog unification

When programming in Prolog, we spend a lot of time thinking about how variables and rules "match" or "are assigned." There are actually two aspects to this. The first, "unification," regards how terms are matched and variables assigned to make terms match. The second, "resolution," is described in separate notes. Resolution is only used if rules are involved. You may notice in these notes that no rules are involved since we are only talking about unification.

### Terms

Prolog has three kinds of **terms**:

1. Constants like 42 (numbers) and franklin (atoms, i.e., lower-case words).
2. Variables like X and Person (words that start with upper-case).
3. Complex terms like parent(franklin, bo) and baz(X, quux(Y))

Two terms **unify** if they can be matched. Two terms can be matched if:

- they are the same term (obviously), or
- they contain variables that can be unified so that the two terms without variables are the same.

For example, suppose our knowledge base is:

```
woman(mia).  
loves(vincent, angela).  
loves(franklin, mia).
```

- mia and mia unify because they are the same.
- mia and X unify because X can be given the value mia so that the two terms (without variables) are the same.
- woman(mia) and woman(X) unify because X can be set to mia which results in identical terms.
- loves(X, mia) and loves(vincent, X) **cannot** unify because there is no assignment for X (given our knowledge base) that makes the two terms identical.
- loves(X, mia) and loves(franklin, X) also cannot unify (can you see why?).

We saw in the Prolog notes that we can "query" the knowledge base and get, say, all the people who love mia. When we query with loves(X, mia). we are asking Prolog to give us all the values for X that unify. These values are, essentially, the people who love mia.

### Rule :

term1 and term2 unify whenever:

1. If term1 and term2 are **constants**, then term1 and term2 unify if and only if they are the same atom, or the same number.
2. If term1 is a **variable** and term2 is any type of term, then term1 and term2 unify, and term1 is instantiated to term2. (And vice versa.) (If they are both variables, they're both instantiated to each other, and we say that they share values.)
3. If term1 and term2 are **complex terms**, they unify if and only if:
  - a. They have the same **functor** and **arity**. The functor is the "function" name (this functor is foo: foo(X, bar)). The arity is the number of arguments for the functor (the arity for foo(X, bar) is 2).
  - b. All of their corresponding arguments unify. **Recursion!**
  - c. The variable instantiations are compatible (i.e., the same variable is not given two different unifications/values).
4. Two terms unify if and only if they unify for one of the above three reasons (there are no reasons left unstated).

### Example

We'll use the = predicate to test if two terms unify. Prolog will answer "Yes" if they do, as well as any sufficient variable assignments to make the unification work.

**Do these two terms unify?**

1.

?- mia = mia.

**o/p Ans:- Yes from Rule 1**

2.

?- mia = X.

**o/p Ans:- Yes, from rule 2.**

3.

?- X = Y.

**o/p Yes, from rule 2.**

4.

?- k(s(g), Y) = k(s(g), X), Y).

**o/p**

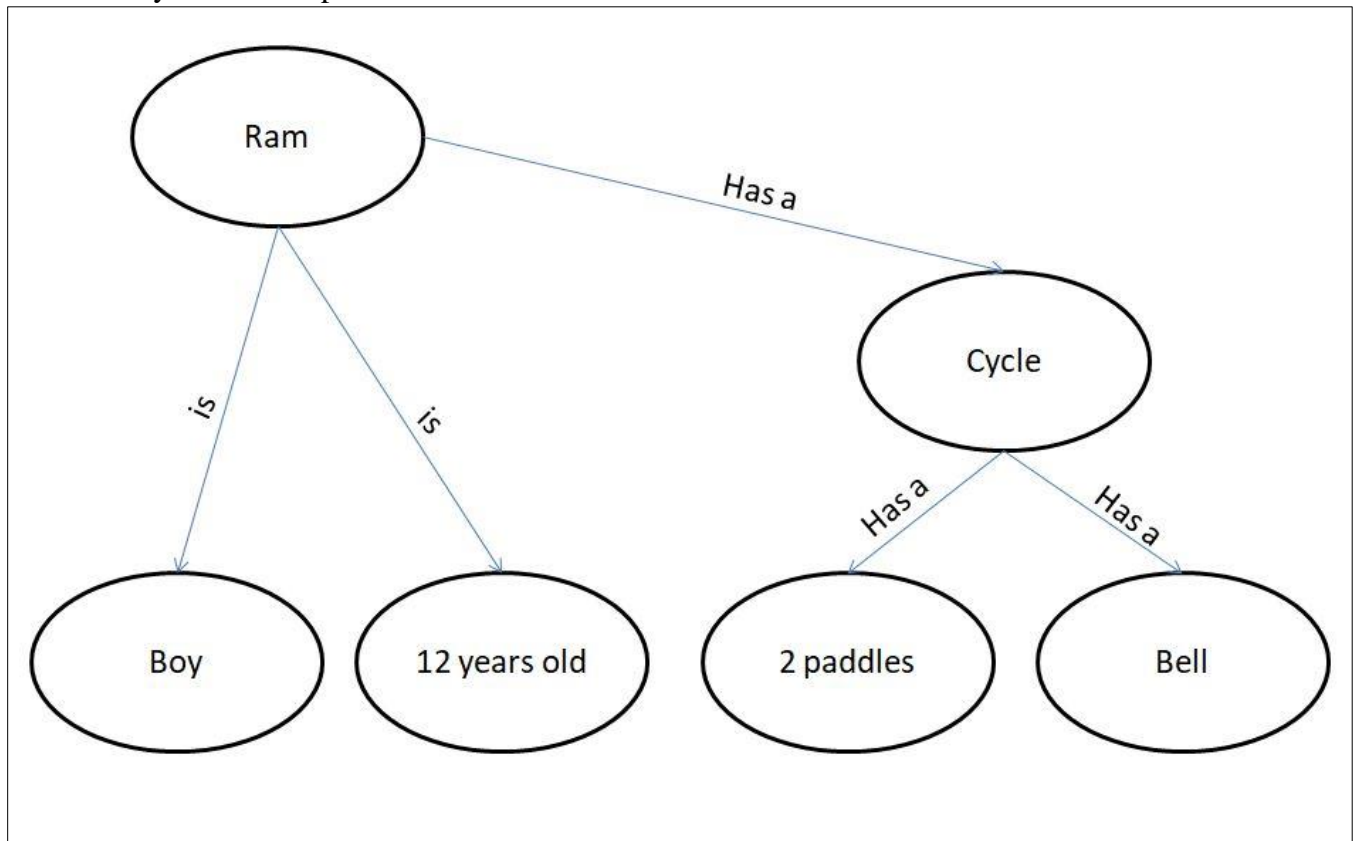

No, these two terms do not unify because arity of  $s(g)$  do not match with the arity of  $s(g,X)$  due to which rule 3 fails in recursion.

## Experiment 8

- **Aim** – Implementation of knowledge representation schemes – use cases.

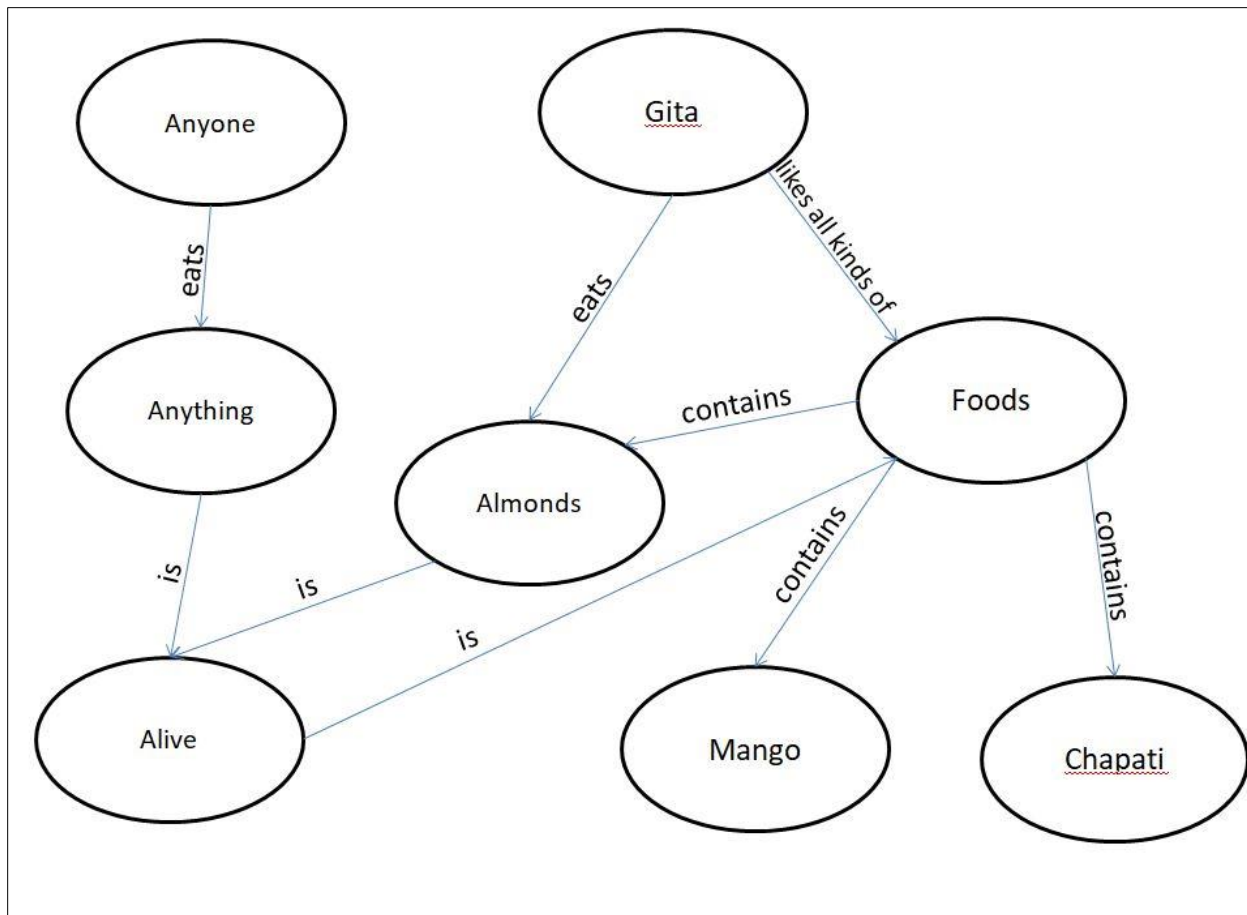

- **Semantic relations** –

1. Ram has a cycle.
2. Ram is a boy.
3. Cycle has a bell.
4. Ram is 12 years old.
5. Cycle has two paddles.

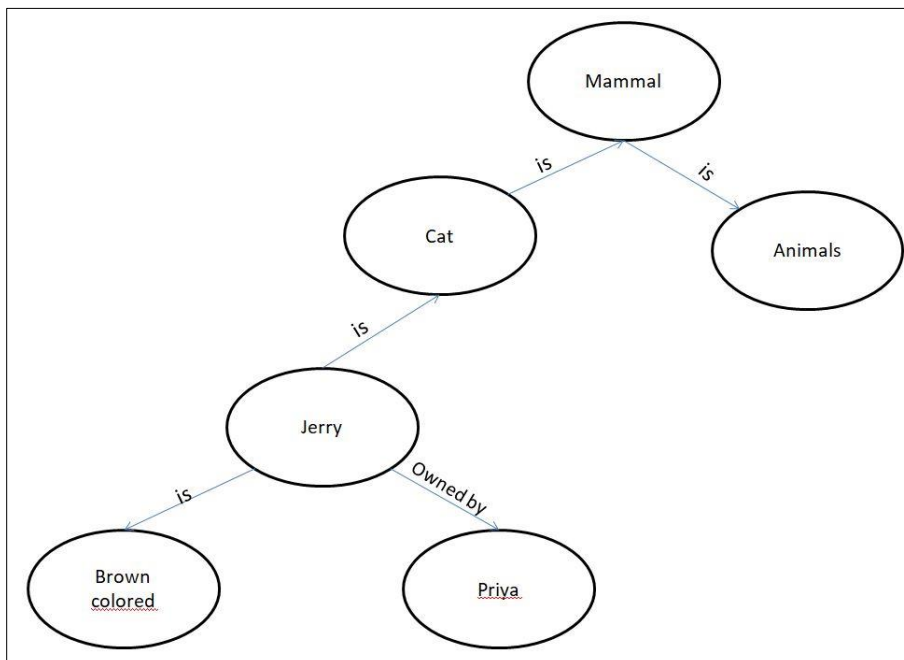

B.

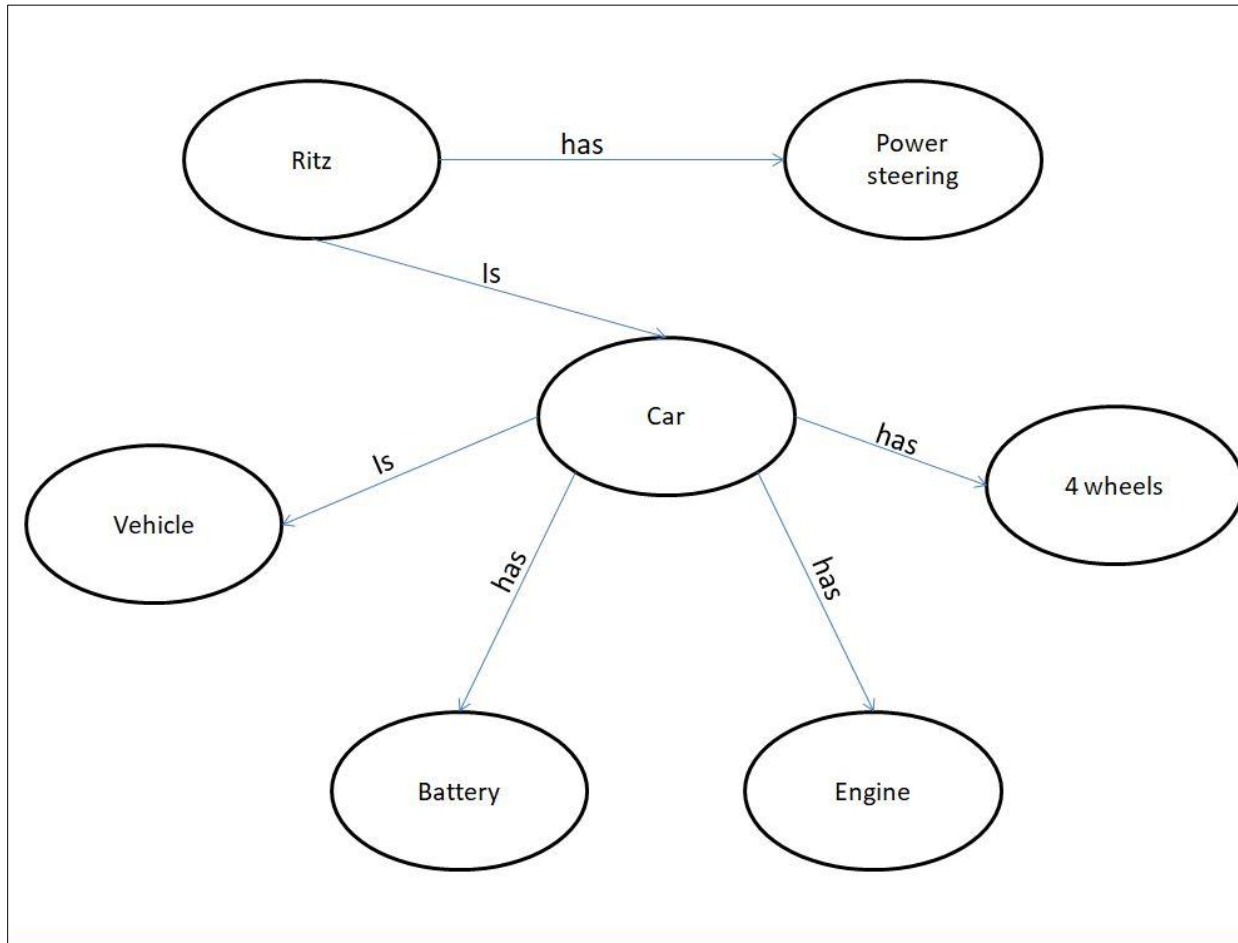

1. Gita likes all kinds of food.
2. Mango and chapati are food.
3. Gita eats almond and is still alive.
4. Anything eaten by anyone and is still alive is food.

- b. 1. Jerry is a cat.  
 2. Jerry is a mammal  
 3. Jerry is owned by Priya.  
 4. Jerry is brown colored.  
 5. All Mammals are animal.

- C.
1. Ritz is a car.
  2. Car has 4 wheels.
  3. Car is a vehicle.
  4. Car has engine.
  5. Car has battery.
  6. Ritz has power steering.

## Experiment 9

- Aim – Implementation of uncertain methods for an application.
- Algorithm–

$$\text{Probability of occurrence} = \frac{\text{Number of desired outcomes}}{\text{Total number of outcomes}}$$

we can find the probability of an uncertain event by using the above formula.

- Code –

### **Problem1:-**

Calculate the Probability of finding how many students got the 60 marks for given data set .

```
import numpy as np
import collections
npArray= np.array([60, 70, 70, 70, 80,90,60])
c=collections.Counter(npArray) # Generate a dictionary {"value":"nbOfOccurrences"}
arraySize=npArray.size
nbOfOccurrences=c[60] #assuming you want the proba to get 10
proba=(nbOfOccurrences/arraySize)*100
print(proba) #print 60.0
output:- 28.57
```

### **Problem2:-**

If In class 80 students and 60 students got 60 % marks then Calculate the Probability of finding how many students got the 60 marks for given data set .

```
#!/usr/bin/env python3
import sys
Marksprob = { }
for line in sys.stdin:
    line = line.strip()
    ClassA, Marks = line.split("\t", 1)
def event_probability(event_outcomes, sample_space):
    probability = (event_outcomes / sample_space) * 100
    return round(probability, 1)
ClassA = 30
Marks = 15
grade_probability = event_probability(Marks, ClassA)
print(str(grade_probability) + '%')
output:48%
```

## RESULT:

The program has been executed successfully.

## Experiment 10

- **Aim** – Implementation of block world problem.

- **Algorithm** –

1. MOVE(B,A)- To lift block from B to A.
2. ON(B,A)- To place block B on A.
3. CLEAR(B)- To lift block B from the table.
4. PLACE(B)- To put the block B on table.

- **Code** –

```
class Strips(object):
    def __init__(self, name, preconds, effects, cost=1):
        self.name = name
        self.preconds = preconds
        self.effects = effects
        self.cost = cost
    def __repr__(self):
        return self.name
class STRIPS_domain(object):
    def __init__(self, feats_vals, actions):
        self.feats_vals = feats_vals
        self.actions = actions
class Planning_problem(object):
    def __init__(self, prob_domain, initial_state, goal):
        self.prob_domain = prob_domain
        self.initial_state = initial_state
        self.goal = goal
boolean = {True, False}
### blocks world
def move(x,y,z):
    """string for the 'move' action"""
    return 'move_'+x+'_from_'+y+'_to_'+z
def on(x):
    """string for the 'on' feature"""
    return x+'_is_on'
def clear(x):
    """string for the 'clear' feature"""
    return 'clear_'+x
def create_blocks_world(blocks = {'a','b','c','d'}):
    blocks_and_table = blocks | {'table'}
    stmap = {Strips(move(x,y,z),{on(x):y, clear(x):True, clear(z):True},
    {on(x):z, clear(y):True, clear(z):False})}
    for x in blocks:
        for y in blocks_and_table:
```

```

for z in blocks:
    if x!=y and y!=z and z!=x:
        stmap.update({ Strips(move(x,y,'table'), { on(x):y, clear(x):True },
            { on(x):'table', clear(y):True })))
for x in blocks:
    for y in blocks:
        for z in blocks:
            if x!=y:
                feats_vals = {on(x):blocks_and_table-{x} for x in blocks}
                feats_vals.update({ clear(x):boolean for x in blocks_and_table})

return STRIPS_domain(feats_vals, stmap)
blocks1dom = create_blocks_world({'a','b','c'})
blocks1 = Planning_problem(blocks1dom,
{on('a'):'table', clear('a'):True,

tower4 = {clear('a'):True, on('a'):'b',
clear('b'):False, on('b'):'c',
clear('c'):False, on('c'):'d',
clear('d'):False, on('d'):'table'}
blocks2 = Planning_problem(blocks2dom,
tower4, # initial state
{on('d'):'c',on('c'):'b',on('b'):'a'}) #goal
blocks3 = Planning_problem(blocks2dom,
tower4, # initial state
{on('d'):'a', on('a'):'b', on('b'):'c'}) #goal

```

- **RESULT:** Goal achieved.
- **Output –**

## Experiment 11

- Aim – Implementation of Learning algorithm.
- Code –

List of Common Machine Learning Algorithms

- Linear Regression
- Logistic Regression
- Decision Tree
- SVM
- Naive Bayes
- KNN
- K-Means
- Random Forest

### 1. KNN (K-Nearest Neighbours)

K-Nearest Neighbors, KNN for short, is a supervised learning algorithm specialized in classification. It is a simple algorithm that stores all available cases and classifies new cases by a majority vote of its k neighbors.

```
from scipy.spatial import distance
```

```
class KNN():
```

```
    def fit(self, X_train, Y_train):
```

```
        self.X_train = X_train
```

```
        self.Y_train = Y_train
```

```
    def predict(self, X_test):
```

```
        predictions = []
```

```
        for row in X_test:
```

```
            label = self.closest(row)
```

```
            predictions.append(label)
```

```
        return predictions
```

```

def closest(self, row):

    best_dist = distance.euclidean(row, self.X_train[0])

    best_index = 0

    for i in range(1, len(self.X_train)):

        dist = distance.euclidean(row, self.X_train[i])

        if dist < best_dist:

            best_dist = dist

            best_index = i

    return self.Y_train[best_index]

from sklearn import datasets

iris = datasets.load_iris()

X = iris.data

Y = iris.target

from sklearn.cross_validation import train_test_split

X_train, X_test, Y_train, Y_test = train_test_split(X, Y, test_size = .75)

from sklearn.neighbors import KNeighborsClassifier

classifier = KNN()

classifier.fit(X_train, Y_train)

predictions = classifier.predict(X_test)

from sklearn.metrics import accuracy_score

```

```
print accuracy_score(Y_test, predictions)
```

OUTPUT::

```
0.9380530973451328
```

## 2. Linear Regression

Linear regression is used to estimate real world values like cost of houses, number of calls, total sales etc.

### Example

The best way to understand linear regression is by considering an example. Suppose we are asked to arrange students in a class in the increasing order of their weights.

```
# sample points
X = [0, 6, 11, 14, 22]
Y = [1, 7, 12, 15, 21]

# solve for a and b
def best_fit(X, Y):
    xbar = sum(X)/len(X)
    ybar = sum(Y)/len(Y)
    n = len(X) # or len(Y)

    numer = sum([xi*yi for xi,yi in zip(X, Y)]) - n * xbar * ybar
    denum = sum([xi**2 for xi in X]) - n * xbar**2

    b = numer / denum
    a = ybar - b * xbar

    print('best fit line:\ny = {:.2f} + {:.2f}x'.format(a, b))

    return a, b

# solution
a, b = best_fit(X, Y)
#best fit line:
#y = 0.80 + 0.92x

# plot points and fit line
import matplotlib.pyplot as plt
plt.scatter(X, Y)
yfit = [a + b * xi for xi in X]
plt.plot(X, yfit)
plt.show()
best fit line:
y = 1.48 + 0.92x
```

- **Output:-**

## Experiment 12

- **Aim** – Development of ensemble model.

- **Code** –

An Ensemble method creates multiple models and combines them to solve it. Ensemble methods help to improve the robustness of the model.

### **Basic Ensemble Techniques**

1 Max Voting

2 Averaging

3 Weighted Average

Problem: Development of ensemble model using Averaging Technique.

**Averaging method:** It is mainly used for regression problems. The method consists of build multiple models independently and returns the average of the prediction of all the models. In general, the combined output is better than an individual output because variance is reduced.

In the below example, three regression models (linear regression, xgboost, and random forest) are trained and their predictions are averaged. The final prediction output is pred\_final.

```
# importing utility modules
import pandas as pd
from sklearn.model_selection import train_test_split
from sklearn.metrics import mean_squared_error

# importing machine learning models for prediction
from sklearn.ensemble import RandomForestRegressor
import xgboost as xgb
from sklearn.linear_model import LinearRegression

# loading train data set in dataframe from train_data.csv file
df = pd.read_csv("train_data.csv")

# getting target data from the dataframe
target = df["target"]

# getting train data from the dataframe
train = df.drop("target")

# Splitting between train data into training and validation dataset
X_train, X_test, y_train, y_test = train_test_split(
    train, target, test_size=0.20)

# initializing all the model objects with default parameters
model_1 = LinearRegression()
model_2 = xgb.XGBRegressor()
model_3 = RandomForestRegressor()

# training all the model on the training dataset
model_1.fit(X_train, y_train)
model_2.fit(X_train, y_train)
```

```
model_3.fit(X_train, y_target)
```

```
# predicting the output on the validation dataset
```

```
pred_1 = model_1.predict(X_test)
```

```
pred_2 = model_2.predict(X_test)
```

```
pred_3 = model_3.predict(X_test)
```

```
# final prediction after averaging on the prediction of all 3 models
```

```
pred_final = (pred_1+pred_2+pred_3)/3.0
```

```
# printing the root mean squared error between real value and predicted value
```

```
print(mean_squared_error(y_test, pred_final))
```

Input:-

	Colleag ue 1	Colleag ue 2	Colleag ue 3	Colleag ue 4	Colleag ue 5	Fina l ratin g
Ratin g	5	4	5	4	4	4.4

Output: - final rating will be 4.4

**RESULT**:Program compiled successfully.

## Experiment 13

- **Aim** – Implementation of NLP problem.

- **Code** –

### **Problem:-**

Count total number of adjective and noun

```
# Import data and tagger
from nltk.corpus import twitter_samples
from nltk.tag import pos_tag_sents

# Load tokenized tweets
tweets_tokens = twitter_samples.tokenized('positive_tweets.json')

# Tag tagged tweets
tweets_tagged = pos_tag_sents(tweets_tokens)

# Set accumulators
JJ_count = 0
NN_count = 0

# Loop through list of tweets
for tweet in tweets_tagged:
    for pair in tweet:
        tag = pair[1]
        if tag == 'JJ':
            JJ_count += 1
        elif tag == 'NN':
            NN_count += 1

# Print total numbers for each adjectives and nouns
print("Total number of adjectives = ", JJ_count)
print("Total number of nouns = ", NN_count)
```

- **Result** –

- Output

```
Total number of adjectives = 6094
Total number of nouns = 13180
```

## **Experiment 14**

**Aim** –Deep learning Project in Python

### **Code-**

```
# Import pandas

import pandas as pd

# Read in white wine data

white      =      pd.read_csv("http://archive.ics.uci.edu/ml/machine-learning-databases/wine-
quality/winequality-white.csv", sep=';')

# Read in red wine data

red        =      pd.read_csv("http://archive.ics.uci.edu/ml/machine-learning-databases/wine-
quality/winequality-red.csv", sep=';')

import matplotlib.pyplot as plt

fig, ax = plt.subplots(1, 2)

ax[0].hist(red.alcohol, 10, facecolor='red', alpha=0.5, label="Red wine")

ax[1].hist(white.alcohol, 10, facecolor='white', ec="black", lw=0.5, alpha=0.5, label="White
wine")

fig.subplots_adjust(left=0, right=1, bottom=0, top=0.5, hspace=0.05, wspace=1)

ax[0].set_ylim([0, 1000])

ax[0].set_xlabel("Alcohol in % Vol")

ax[0].set_ylabel("Frequency")

ax[1].set_xlabel("Alcohol in % Vol")

ax[1].set_ylabel("Frequency")

#ax[0].legend(loc='best')

#ax[1].legend(loc='best')
```

```
fig.suptitle("Distribution of Alcohol in % Vol")
```

```
plt.show()
```

## **Output:**
